

ECC006 HOMEWORK 7

WEB RESEARCH

When examining web content accessibility and mobile web design, we can see that both serve the same purpose. They aim to ensure ease of use, regardless of whether the evaluation is based on software or physical factors. Images or headings can serve as examples because they help users access information more quickly and also facilitate loading on mobile devices. Additionally, when we develop a website for people with disabilities, we also ensure ease of use for other users. This creates a significant overlap, allowing web developers to support both platforms simultaneously. At the forefront of these challenges are environmental and visual limitations. An individual with visual impairment and an individual who struggles to see due to reflections in bright light experience similar difficulties. Therefore, web developers can overcome these obstacles for both individuals by taking these factors into account. In terms of title structure, screen reader devices can analyze the page audibly, providing quick information access to the screen where space is insufficient. Images and subtext can be used to prevent confusion and loss of content. Because subtext provides information to readers, and if the image doesn't load in case of a possible internet speed loss, they will still have the information. For individuals with limited motor skills and those who use the phone with one hand in daily life, a large, easily clickable touchscreen instead of a small one provides ease of use for both sides.

Developers can meet the needs of both mobile users and individuals with disabilities simultaneously by using Responsive Design and WCAG standards as a guide.

In conclusion, accessibility is not just a necessity, but a way to provide a higher quality user experience for everyone in the mobile world.
